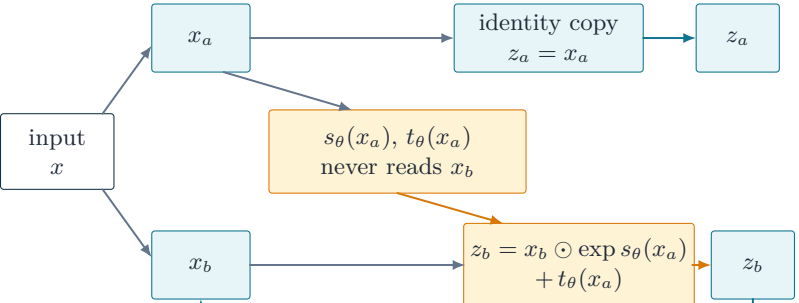
One coupling layer: forward and exact inverse



$x_a = z_a, \quad x_b = \big(z_b - t_\theta(z_a)\big) \odot \exp[-s_\theta(z_a)]$

closed form: it re-uses the same s_θ, t_θ, now read at z_a

Block-triangular Jacobian $\partial z / \partial x$

	x_a	x_b
z_a	I	0
z_b	$\dfrac{\partial z_b}{\partial x_a}$	diag $\exp s_\theta(x_a)$

$\log|\det J| = \sum_j s_{\theta,j}(x_a)$

block-triangular: $\det = \det(I)\det(D)$

so only the diagonal blocks matter

layer 1	x_a copy	x_b affine
layer 2	x_a affine	x_b copy

masks alternate each layer
